In June 2013, indoor air quality was assessed in Vicksburg and Natchez. Neither community has an ordinance regarding smoking.

We used a TSI SidePak AM510 Personal Aerosol Monitor using the protocol developed by the Roswell Park Cancer Institute to measure the concentration of fine particle air pollution, PM$_{2.5}$. Air quality studies typically monitor particles of this size because PM$_{2.5}$ are released in significant amounts from burning cigarettes, are easily inhaled deep into the lungs, and cause a variety of adverse health effects including cardiovascular and respiratory morbidity and death.
According to the Surgeon General, there is no safe level of exposure to secondhand smoke. Tobacco smoke contains more than 7,000 chemicals, of which at least 69 cause cancer. Acute risks of secondhand smoke exposure include sudden infant death syndrome, acute respiratory problems, otitis media, increased asthma severity, and myocardial infarction. The numerous chronic and acute harms of tobacco smoke have been documented in many literature reviews.

Tobacco smoke contains more than 7,000 chemical compounds. More than 250 of these chemicals are known to be harmful, and at least 69 are known to cause cancer. SHS has been linked to lung cancer. There is also some evidence suggesting it may be linked with childhood leukemia and cancers of the larynx (voice box), pharynx (throat), brain, bladder, rectum, stomach, and breast.

Current Study
Mississippi is one of the few states that has not passed a statewide law regulating smoking in public indoor places. However, several municipalities in this state have passed local ordinances restricting smoking. Currently, 71 municipalities have implemented 100% comprehensive smoke-free ordinances and 12 have passed partial ordinances.

The goal of this study was to measure the level of fine particle air pollution in restaurants where smoking was permitted and compare this to smoke-free locations. Specifically, we examined indoor particle air pollution levels in locations where smoking is not allowed at all, non-smoking areas within locations that allow smoking, and locations where smoking is allowed in all places.
Air quality is assessed based on Particulate Matter (PM). The size of particles is directly linked to their potential for causing health problems. Very small particles generally pass through the throat and nose and enter the lungs. Once inhaled, these particles can affect the heart and lungs and cause serious health effects. Air quality levels are defined as the mass of particulate matter ≤2.5 microns in diameter in a volume of air: micrograms per cubic meter (μg/m3). A microgram is one millionth of a gram. A cubic meter (approximately 39” X 39” X 39”) describes a volume of air that is about the size of a washing machine.
We used a TSI SidePak Monitor using the protocol developed by the Roswell Park Cancer Institute\textsuperscript{3} to measure the concentration of fine particle air pollution. The specific class of RSPs monitored was particulate matter ≤2.5 microns in diameter (PM\textsubscript{2.5}), a commonly used marker for tobacco smoke exposure\textsuperscript{4,5}. Air quality studies typically monitor particles of this size because PM\textsubscript{2.5} are released in significant amounts from burning cigarettes, are easily inhaled deep into the lungs, and cause a variety of adverse health effects including cardiovascular and respiratory morbidity and death.

**THE ROSWELL PARK CANCER INSTITUTE PROTOCOL\textsuperscript{6}**

The number of people inside the venue and the number of burning cigarettes were recorded during sampling. These observations were averaged over the time inside the venue to determine the average number of people on the premises and the average number of burning cigarettes. Room dimensions were also determined using a combination of counting construction materials of a known size such as floor tiles or estimation. Room volumes were calculated from these dimensions.

A TSI SidePak AM\textsubscript{510} Personal Aerosol Monitor (TSI, Inc., St. Paul, MN) was used to sample and record the levels of respirable suspended particles in the air. The SidePak uses a built-in sampling pump to draw air through the device where the particulate matter in the air scatters the light from a laser. This portable light-scattering aerosol monitor was fitted with a 2.5 μm impactor in order to measure the concentration of particulate matter with a mass-median aerodynamic diameter less than or equal to 2.5 μm, or PM\textsubscript{2.5}. Tobacco smoke particles are almost exclusively less than 2.5 μm with a mass-median diameter of 0.2 μm. The Sidepak was used with a calibration factor setting of 0.32, suitable for secondhand smoke. In addition, the SidePak was zero-calibrated prior to each use by attaching a HEPA filter according to the manufacturer’s specifications.

Sampling was discreet in order not to disturb the occupants’ normal behavior. For each venue, the first and last minute of logged data were removed because they are averaged with outdoor and entryway air. The remaining data points were averaged to provide an average PM\textsubscript{2.5} concentration within the venue.

CONCLUSION

This study demonstrates that employees and patrons in Mississippi venues permitting indoor smoking are exposed to harmful levels of indoor air pollution resulting from indoor smoking. A comprehensive smoke-free air policy that prohibits indoor smoking in all indoor places is the only proven means to eliminate this exposure to toxic tobacco smoke pollution. This type of policy will result in improved quality of life and health outcomes for Mississippi workers and residents.

ACKNOWLEDGEMENTS

The study was funded by the American Lung Association Gulf-Plains Region. The protocol for this study and the report approach were developed by the Roswell Park Cancer Institute (RPCI).
